## Abstract

The classical Frobenius problem is to compute the largest number  $g$  not representable as a non-negative integer linear combination of non-negative integers  $x_1, x_2, \dots, x_k$ , where  $\gcd(x_1, x_2, \dots, x_k) = 1$ . In this paper we consider generalizations of the Frobenius problem to the noncommutative setting of a free monoid. Unlike the commutative case, where the bound on  $g$  is quadratic, we are able to show exponential or subexponential behavior for an analogue of  $g$ , depending on the particular measure chosen.

## 1 Introduction

Let  $x_1, x_2, \dots, x_k$  be positive integers. It is well-known that every sufficiently large integer can be written as a non-negative integer linear combination of the  $x_i$  if and only if  $\gcd(x_1, x_2, \dots, x_k) = 1$ .

The *Frobenius problem* (so-called because, according to Brauer [2], “Frobenius mentioned it occasionally in his lectures”) is the following:

Given positive integers  $x_1, x_2, \dots, x_k$  with  $\gcd(x_1, x_2, \dots, x_k) = 1$ , find the largest positive integer  $g(x_1, x_2, \dots, x_k)$  which *cannot* be represented as a non-negative integer linear combination of the  $x_i$ .

**Example 1.** *The Chicken McNuggets Problem* ([29, pp. 19-20, 233–234], [22]). If Chicken McNuggets can be purchased at McDonald’s only in quantities of 6, 9, or 20 pieces, what is the largest number of McNuggets that cannot be purchased? The answer is  $g(6, 9, 20) = 43$ .

Although it seems simple at first glance, the Frobenius problem on positive integers has many subtle and intriguing aspects that continue to elicit study. A recent book by Ramírez Alfonsín [24] lists over 400 references on this problem. Applications to many different fields exist: to algebra [19]; the theory of matrices [11], counting points in polytopes [1]; the problem of efficient sorting using Shellsort [16, 25, 30, 26]; the theory of Petri nets [28]; the liveness of weighted circuits [8]; etc.

Generally speaking, research on the Frobenius problem can be classified into three different areas:

- Formulas or algorithms for the exact computation of  $g(x_1, \dots, x_k)$ , including formulas for  $g$  where the  $x_i$  obey certain relations, such as being in arithmetic progression;
- The computational complexity of the problem;
- Good upper or lower bounds on  $g(x_1, \dots, x_k)$ .

For  $k = 2$ , it is folklore that

$$g(x_1, x_2) = x_1 x_2 - x_1 - x_2; \tag{1}$$

this formula is often attributed to Sylvester [27], although he did not actually state it. Eq. (1) gives an efficient algorithm to compute  $g$  for two elements. For  $k = 3$ , efficient algorithms have been given by Greenberg [14] and Davison [10]; if  $x_1 < x_2 < x_3$ , these algorithms run in time bounded by a polynomial in  $\log x_3$ . Kannan [17, 18] gave a very complicated algorithm that runs in polynomial time in  $\log x_k$  if  $k$  is fixed, but is wildly exponential in  $k$ . However, Ramírez Alfonsín [23] proved that the general problem is NP-hard, under Turing reductions, by reducing from the integer knapsack problem. So it seems very likely that there is no simple formula for computing  $g(x_1, x_2, \dots, x_k)$  for arbitrary  $k$ . Nevertheless, recent work by Einstein, Lichtblau, Strzebonski, and Wagon [12] shows that in practice the Frobenius number can be computed relatively efficiently, even for very large numbers, at least for  $k \leq 8$ .

Another active area of interest is estimating how big  $g$  is in terms of  $x_1, x_2, \dots, x_k$  for  $x_1 < x_2 < \dots < x_k$ . It is known, for example, that  $g(x_1, x_2, \dots, x_k) < x_k^2$ . This follows from Wilf's algorithm [31]. Many other bounds are known.

One can also study variations on the Frobenius problem. For example, given positive integers  $x_1, x_2, \dots, x_k$  with  $\gcd(x_1, x_2, \dots, x_k) = 1$ , what is the number  $f(x_1, x_2, \dots, x_k)$  of positive integers not represented as a non-negative integer linear combination of the  $x_i$ ? Sylvester, in an 1884 paper [27], showed that  $f(x_1, x_2) = \frac{1}{2}(x_1 - 1)(x_2 - 1)$ .

Our goal in this paper is to generalize the Frobenius problem to the setting of a free monoid. In this framework, we start with a finite, nonempty alphabet  $\Sigma$ , and consider the set of all finite words  $\Sigma^*$ . Instead of considering integers  $x_1, x_2, \dots, x_k$ , we consider words  $x_1, x_2, \dots, x_k \in \Sigma^*$ . Instead of considering linear combinations of integers, we instead consider the languages  $\{x_1, x_2, \dots, x_k\}^*$  and  $x_1^* x_2^* \dots x_k^*$ . Actually, we consider several additional generalizations, which vary according to how we measure the size of the input, conditions on the input, and measures of the size of the result. For an application of the noncommutative Frobenius problem, see Clément, Duval, Guaiana, Perrin, and Rindone [9].

In order to motivate our definitions, we consider the easiest case first: where  $\Sigma = \{0\}$ , a unary alphabet.

## 2 The unary case

Suppose  $x_i = 0^{a_i}$ , for  $1 \leq i \leq k$ . The Frobenius problem is evidently linked to many problems over unary languages. It figures, for example, in estimating the size of the smallest DFA equivalent to a given NFA [7].

If  $L \subseteq \Sigma^*$ , by  $\overline{L}$  we mean  $\Sigma^* - L$ , the complement of  $L$ . If  $L$  is a finite language, by  $|L|$  we mean the cardinality of  $L$ . Evidently we have

**Proposition 2.** *Suppose  $x_i = 0^{a_i}$  for  $1 \leq i \leq k$ , and write  $S = \{x_1, x_2, \dots, x_k\}$ . Then  $S^*$  is co-finite if and only  $\gcd(a_1, a_2, \dots, a_k) = 1$ . Furthermore, if  $S^*$  is co-finite, then the length of the longest word in  $\overline{S^*}$  is  $g(a_1, a_2, \dots, a_k)$ , and  $|\overline{S^*}| = f(a_1, a_2, \dots, a_k)$ .*

This result suggests that one appropriate noncommutative generalization of the condition  $\gcd(a_1, a_2, \dots, a_k) = 1$  is that  $S^* = \{x_1, x_2, \dots, x_k\}^*$  be co-finite, and one appropriate generalization of the  $g$  function is the length of the longest word not in  $S^*$ .

But there are other possible generalizations. Instead of measuring the length of the longest omitted word, we could instead consider the *state complexity* of  $S^*$ . By the state complexity of a regular language  $L$ , written  $\text{sc}(L)$ , we mean the number of states in the (unique) minimal deterministic finite automaton (DFA) accepting  $L$ . In the unary case, this alternate measure has a nice expression in terms of the ordinary Frobenius function:

**Theorem 3.** *Let  $\gcd(a_1, a_2, \dots, a_k) = 1$ . Then*

$$\text{sc}(\{0^{a_1}, 0^{a_2}, \dots, 0^{a_k}\}^*) = g(a_1, a_2, \dots, a_k) + 2.$$

*Proof.* Since  $\gcd(a_1, a_2, \dots, a_k) = 1$ , every word of length  $> g(a_1, a_2, \dots, a_k)$  will be in the set  $\{0^{a_1}, 0^{a_2}, \dots, 0^{a_k}\}^*$ . Thus we can accept  $\{0^{a_1}, 0^{a_2}, \dots, 0^{a_k}\}^*$  with a DFA having  $g(a_1, \dots, a_k) + 2$  states, using a “tail” of  $g(a_1, \dots, a_k) + 1$  states and a “loop” of one accepting state. Thus  $\text{sc}(\{0^{a_1}, 0^{a_2}, \dots, 0^{a_k}\}^*) \leq g(a_1, a_2, \dots, a_k) + 2$ .

To see  $\text{sc}(\{0^{a_1}, 0^{a_2}, \dots, 0^{a_k}\}^*) \geq g(a_1, a_2, \dots, a_k) + 2$ , we show that the words

$$\epsilon, 0, 0^2, \dots, 0^{g(a_1, \dots, a_k)+1}$$

are pairwise inequivalent under the Myhill-Nerode equivalence relation. Pick  $0^i$  and  $0^j$ ,  $0 \leq i < j \leq g(a_1, \dots, a_k) + 1$ . Let  $L = \{0^{a_1}, 0^{a_2}, \dots, 0^{a_k}\}^*$ . Choose  $z = 0^{g(a_1, \dots, a_k)-i}$ . Then  $0^i z = 0^{g(a_1, \dots, a_k)} \notin L$ , while  $0^j z = 0^{g(a_1, \dots, a_k)+j-i} \in L$ , since  $j > i$ .  $\square$

**Corollary 4.** *Let  $\gcd(a_1, \dots, a_k) = d$ . Then*

$$\text{sc}(\{0^{a_1}, 0^{a_2}, \dots, 0^{a_k}\}^*) = d(g(a_1/d, a_2/d, \dots, a_k/d) + 1) + 1.$$

Hence it follows that  $\text{sc}(\{0^{a_1}, 0^{a_2}, \dots, 0^{a_k}\}^*) = O(a_k^2)$ . Furthermore, this bound is essentially optimal; since  $g(n, n+1) = n^2 - n - 1$ , there exist examples with  $\text{sc}(\{0^{a_1}, 0^{a_2}, \dots, 0^{a_k}\}^*) = \Omega(a_k^2)$ .

### 3 The case of larger alphabets

We now turn to the main results of the paper. Given as input a list of words  $x_1, x_2, \dots, x_k$ , not necessarily distinct, and defining  $S = \{x_1, x_2, \dots, x_k\}$ , we can measure the size of the input in a number of different ways:

- (a)  $k$ , the number of words;
- (b)  $n = \max_{1 \leq i \leq k} |x_i|$ , the length of the longest word;
- (c)  $m = \sum_{1 \leq i \leq k} |x_i|$ , the total number of symbols;
- (d)  $\text{sc}(\{x_1, x_2, \dots, x_k\})$ , the state complexity of the language represented by the input.
- (e)  $\text{nsc}(\{x_1, x_2, \dots, x_k\})$ , the nondeterministic state complexity of the language represented by the input.

We may impose various conditions on the input:

- (i) Each  $x_i$  is defined over the unary alphabet;
- (ii)  $S^* = \{x_1, x_2, \dots, x_k\}^*$  is co-finite
- (iii)  $k = 2$ ;
- (iv)  $k$  is fixed.

And finally, we can explore various measures on the size of the result:

- 1.  $\mathcal{L} = \max_{x \in \Sigma^* - S^*} |x|$ , the length of the longest word not in  $S^*$ ;
- 2.  $\mathcal{K} = \max_{x \in \Sigma^* - x_1^* x_2^* \dots x_k^*} |x|$ , the length of the longest word not in  $x_1^* x_2^* \dots x_k^*$ ;
- 3.  $\mathcal{S} = \text{sc}(S^*)$ , the state complexity of  $S^*$ ;
- 4.  $\mathcal{N} = \text{nsc}(S^*)$ , the nondeterministic state complexity of  $S^*$ ;
- 5.  $\mathcal{M} = |\Sigma^* - S^*|$ , the number of words not in  $S^*$ ;
- 6.  $\mathcal{S}' = \text{sc}(x_1^* x_2^* \dots x_k^*)$ ;
- 7.  $\mathcal{N}' = \text{nsc}(x_1^* x_2^* \dots x_k^*)$

Clearly not every combination results in a sensible question to study. In order to study  $\mathcal{L}$ , the length of the longest word omitted by  $S^*$ , we clearly need to impose condition (ii), that  $S^*$  be co-finite.

We now study under what conditions it makes sense to study  $\mathcal{K} = \max_{x \in \Sigma^* - x_1^* x_2^* \dots x_k^*} |x|$ , the length of the longest word not in  $x_1^* x_2^* \dots x_k^*$ .

**Theorem 5.** *Let  $x_1, x_2, \dots, x_k \in \Sigma^+$ . Then  $L = x_1^* x_2^* \cdots x_k^*$  is co-finite if and only if  $|\Sigma| = 1$  and  $\gcd(|x_1|, \dots, |x_k|) = 1$ .*

*Proof.* If  $|\Sigma| = 1$  and  $\gcd(|x_1|, \dots, |x_k|) = 1$ , then a unary word of every sufficiently long length can be attained by concatenations of the  $x_i$ , so  $L$  is co-finite.

For the other direction, suppose  $L$  is co-finite. If  $|\Sigma| = 1$ , let  $\gcd(|x_1|, \dots, |x_k|) = d$ . If  $d > 1$ ,  $L$  contains only words of length divisible by  $d$ , and so is not-cofinite. So  $d = 1$ .

Hence assume  $|\Sigma| \geq 2$ , and let  $a, b$  be distinct letters in  $\Sigma$ . Let  $l = \max_{1 \leq i \leq k} |x_i|$ , the length of the longest word. Let  $L' = ((a^{2l}b^{2l})^k)^+$ . Then we claim that  $L' \cap L = \emptyset$ . For if none of the  $x_i$  consist of powers of a single letter, then the longest block of consecutive identical letters in any word in  $L$  is  $< 2l$ , so no word in  $L'$  can be in  $L$ . Otherwise, say some of the  $x_i$  consist of powers of a single letter. Take any word  $w$  in  $L$ , and count the number  $n(w)$  of maximal blocks of  $2l$  or more consecutive identical letters in  $w$ . (Here “maximal” means such a block is delimited on both sides by either the beginning or end of the word, or a different letter.) Clearly  $n(w) \leq k$ . But  $n(w') \geq 2k$  for any word in  $L'$ . Thus  $L$  is not co-finite, as it omits all the words in  $L'$ .  $\square$

## 4 State complexity results

In this section we study the measures  $\mathcal{S} = \text{sc}(S^*)$ ,  $\mathcal{N} = \text{nsc}(S^*)$ , and  $\mathcal{S}' = \text{sc}(x_1^* x_2^* \cdots x_k^*)$ . consider some results on state complexity. First we review previous results.

Yu, Zhuang, and Salomaa [32] showed that if  $L$  is accepted by a DFA with  $n$  states, then  $L^*$  can be accepted by a DFA with at most  $2^{n-1} + 2^{n-2}$  states. Furthermore, they showed this bound is realized, in the sense that for all  $n \geq 2$ , there exists a DFA  $M$  with  $n$  states such that the minimal DFA accepting  $L(M)^*$  needs  $2^{n-1} + 2^{n-2}$  states. This latter result was given previously by Maslov [21].

Câmpeanu, Culik, Salomaa, and Yu [3, 5] showed that if a DFA with  $n$  states accepts a *finite* language  $L$ , then  $L^*$  can be accepted by a DFA with at most  $2^{n-3} + 2^{n-4}$  states for  $n \geq 4$ . Furthermore, this bound is actually achieved for  $n > 4$  for an alphabet of size 3 or more. Unlike the examples we are concerned with in this section, however, the finite languages they construct contain exponentially many words in  $n$ .

Holzer and Kutrib [15] examined the nondeterministic state complexity of Kleene star. They showed that if an NFA  $M$  with  $n$  states accepts  $L$ , then  $L^*$  can be accepted by an NFA with  $n + 1$  states, and this bound is tight. If  $L$  is finite, then  $n - 1$  states suffices, and this bound is tight.

Câmpeanu and Ho [4] gave tight bounds for the number of states required to accept a finite language whose words are all bounded by length  $n$ .

**Proposition 6.**

$$(a) \text{ nsc}(\{x_1, x_2, \dots, x_k\}^*) \leq m - k + 1.$$

$$(b) \text{ sc}(\{x_1, x_2, \dots, x_k\}^*) \leq 2^{m-k+1}.$$

(c) If no  $x_i$  is a prefix of any other  $x_j$ , then  $\text{sc}(\{x_1, x_2, \dots, x_k\}^*) \leq m - k + 2$ .

*Proof.* (a) Form an NFA from the trie for the words  $x_1, \dots, x_k$ , sharing a common initial state  $q_0$ , and having the transition on the last letter of each word go back to  $q_0$ . This NFA will have  $m - k + 1$  nodes.

(b) Take the NFA from part (a) and apply the subset construction.

(c) If no  $x_i$  is a prefix of any other  $x_j$ , then the NFA constructed in part (a) is actually a DFA. One extra state is needed as a “dead” state. □

We now consider an example providing a lower bound for the state complexity of  $\{x_1, x_2, \dots, x_k\}^*$ . Let  $t$  be an integer  $\geq 2$ , and define words as follows:

$$\begin{aligned} y &:= 01^{t-1}0 \\ x_i &:= 1^{t-i-1}01^{i+1}, \quad 0 \leq i \leq t-2. \end{aligned}$$

Let  $S_t := \{0, x_0, x_1, \dots, x_{t-2}, y\}$ .

Thus, for example,

$$S_6 := \{0, 1111101, 1111011, 1110111, 1101111, 1011111, 0111110\}.$$

**Theorem 7.**  $S_t^*$  has state complexity  $3t2^{t-2} + 2^{t-1}$ .

The proof of this theorem is rather complicated, so we give a proof of the following slightly weaker result:

**Theorem 8.**  $\text{sc}(S_t^*) \geq 2^{t-2}$ .

*Proof.* First, we create an NFA  $M_t$  with  $3t - 1$  states that accepts  $S_t^*$ . This NFA has states

$$Q = \{p_0, p_1, \dots, p_t, q_1, q_2, \dots, q_{t-1}, r_1, r_2, \dots, r_{t-1}\}$$

with only one final state  $F = \{p_0\}$ .

For example, here is the NFA  $M_6$ .

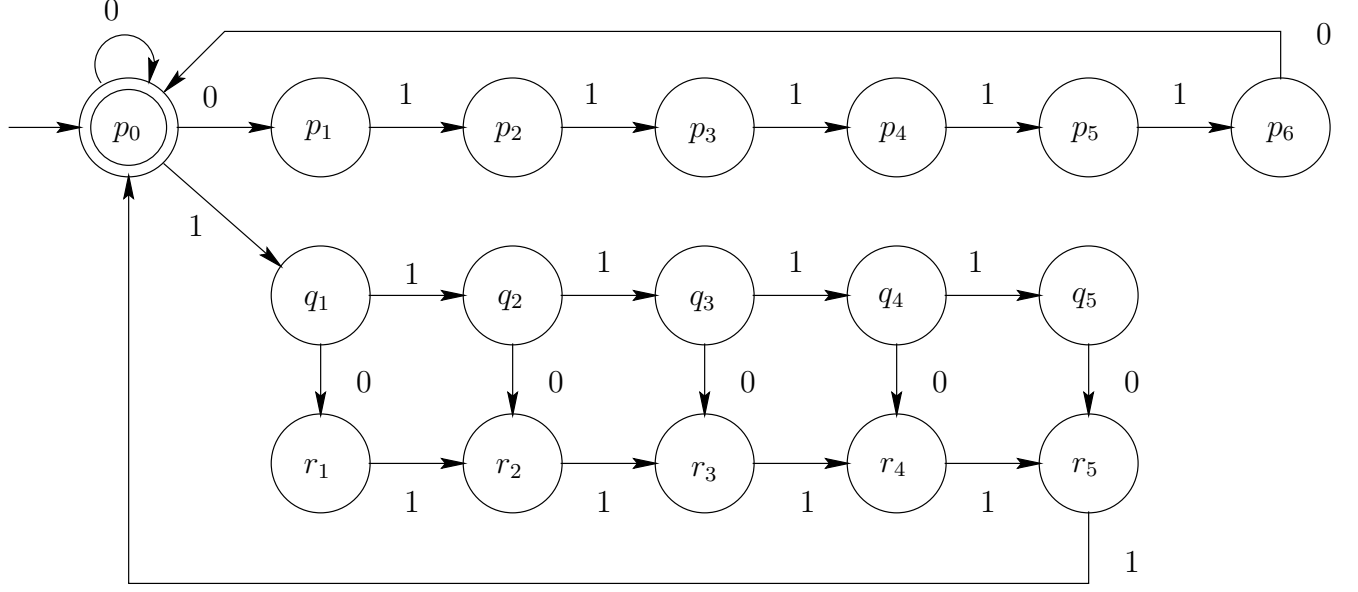

Figure 1: The NFA  $M_6$

We now determine  $\delta(q, z)$  for each state  $q$  of  $M_t$  and each element of  $z \in S_t$ . The reader can verify that

$$\begin{aligned}
\delta(p_0, y) &= \{r_{t-1}, p_0\} \\
\delta(p_0, x_i) &= \{p_0\}, \quad 1 \leq i \leq t-2 \\
\delta(p_i, x_j) &= \begin{cases} q_i, & \text{if } j = i-1; \\ \emptyset, & \text{otherwise.} \end{cases} \\
\delta(p_t, y) &= \{r_{t-1}\} \\
\delta(q_1, y) &= \{p_0, p_1\} \\
\delta(q_i, y) &= \{r_{i-1}\}, \quad 2 \leq i \leq t-1 \\
\delta(q_i, x_j) &= \begin{cases} q_i, & \text{if } j \geq i; \\ \emptyset, & \text{otherwise.} \end{cases} \quad \text{for } 1 \leq i \leq t-1, 0 \leq j \leq t-2 \\
\delta(r_i, y) &= \emptyset, \quad 1 \leq i \leq t-1 \\
\delta(r_i, x_j) &= \begin{cases} \{q_i, p_{j+1}\}, & \text{if } j = i-1; \\ \{r_i\}, & \text{if } j < i-1; \\ \emptyset, & \text{otherwise.} \end{cases} \quad \text{for } 1 \leq i \leq t-1, 0 \leq j \leq t-2
\end{aligned}$$

From these relations, we deduce that

$$\begin{aligned}
\delta(\{q_i, q_{i+1}, \dots, q_{t-1}, p_t, p_0\}, y) &= \{r_{i-1}, r_i, \dots, r_{t-1}, p_0\} \\
\delta(\{r_{i+1}, r_{i+2}, \dots, r_{t-1}, p_0\}, x_i) &= \{q_{i+1}, p_{i+2}, r_{i+2}, r_{i+3}, \dots, r_{t-1}, p_0\} \\
\delta(\{q_i, q_{i+1}, \dots, q_j, p_{j+1}, r_{j+1}, r_{j+2}, \dots, r_{t-1}, p_0\}, x_j) &= \{q_i, q_{i+1}, \dots, q_{j+1}, p_{j+2}, r_{j+2}, r_{j+3}, \dots, r_{t-1}, p_0\}, \\
&\quad \text{if } i \leq j \leq t-3 \\
\delta(\{q_i, q_{i+1}, \dots, q_{t-2}, p_{t-1}, r_{t-1}, p_0\}, x_j) &= \{q_i, q_{i+1}, \dots, q_{t-1}, p_t, r_{t-1}, p_0\}
\end{aligned}$$

Let  $T$  be any subset of  $\{r_1, r_2, \dots, r_{t-2}\}$ , and write  $T = \{r_{i_1}, r_{i_2}, \dots, r_{i_j}\}$  for  $j$  indices

$$1 \leq i_1 < i_2 < \dots < i_j \leq t-2.$$

We claim that the  $2^{t-2}$  words

$$y \ x_{t-2}y \ x_{t-3}x_{t-2}y \ x_{t-4}x_{t-3}x_{t-2}y \ \dots \ x_1x_2 \dots x_{t-2}y \ x_{i_1}x_{i_2} \dots x_{i_j}y$$

where

$$1 \leq i_1 < i_2 < \dots < i_j \leq t-2,$$

are pairwise inequivalent under the Myhill-Nerode equivalence relation.

To show this, we first argue that any subset of states of the form  $T' := \{p_0, r_{t-1}\} \cup T$ , where  $T$  is as in the previous paragraph, is reachable from  $p_0$ . From the relations above we see that the following path reaches  $T'$ :

$$\begin{aligned}
&\{p_0\} \xrightarrow{y} \{p_0, r_{t-1}\} \xrightarrow{x_{t-2}} \{q_{t-1}, p_t, p_0\} \xrightarrow{y} \{r_{t-2}, r_{t-1}, p_0\} \xrightarrow{x_{t-3}} \\
&\{q_{t-2}, p_{t-1}, r_{t-1}, p_0\} \xrightarrow{x_{t-2}} \{q_{t-2}, q_{t-1}, p_t, p_0\} \xrightarrow{y} \{r_{t-3}, r_{t-2}, r_{t-1}, p_0\} \xrightarrow{x_{t-4}} \\
&\{q_{t-3}, p_{t-2}, r_{t-2}, r_{t-1}, p_0\} \xrightarrow{x_{t-3}} \{q_{t-3}, q_{t-2}, p_{t-1}, r_{t-1}, p_0\} \xrightarrow{x_{t-2}} \{q_{t-3}, q_{t-2}, q_{t-1}, p_t, p_0\} \xrightarrow{y} \\
&\{r_{t-4}, r_{t-3}, r_{t-2}, r_{t-1}, p_0\} \dots \\
&\xrightarrow{x_1x_2 \dots x_{t-2}y} \{p_0, r_1, r_2, \dots, r_{t-1}\} \\
&\xrightarrow{x_{i_1}x_{i_2} \dots x_{i_j}y} \{r_{i_1}, r_{i_2}, \dots, r_{i_j}, r_{t-1}, p_0\}.
\end{aligned}$$

Finally, we argue that each of these subsets of states is inequivalent. This is because given two distinct such subsets, say  $T'$  and  $T''$ , there must be an  $r_i$ ,  $1 \leq i \leq t-2$ , that is contained in one (say  $T'$ ) but not the other. Then reading the word  $1^{t-i}$  takes  $T'$  to  $p_0$ , but not  $T''$ .  $\square$

**Corollary 9.** *There exists a family of sets  $S_t$ , each consisting of  $t+1$  words of length  $\leq t+1$ , such that  $\text{sc}(S_t^*) = 2^{\Omega(t)}$ . If  $m$  is the total number of symbols in these words, then  $\text{sc}(S_t^*) = 2^{\Omega(\sqrt{m})}$ .*

Using the ideas in the previous proof, we can also create an example achieving subexponential state complexity for  $x_1^* x_2^* \cdots x_k^*$ .

**Theorem 10.** *As before, define*

$$\begin{aligned} y &:= 01^{t-1}0 \\ x_i &:= 1^{t-i-1}01^{i+1}, \quad 0 \leq i \leq t-2. \end{aligned}$$

Let  $L = (0^* x_1^* x_2^* \cdots x_{n-1}^* y^*)^e$  where  $e = (t+1)(t-2)/2 + 2t$ . Then  $\text{sc}(L) \geq 2^{t-2}$ .

*Proof.* Define  $A = \{x_0, x_1, \dots, x_{t-2}, y, 0\}$  and  $T = \{x_1, x_2, \dots, x_{t-2}\}$ . For any subset  $S$  of  $T$ , say  $\{s_1, s_2, \dots, s_j\}$  with  $s_1 < s_2 < \cdots < s_j$  define

$$x(S) = yx_{t-2}yx_{t-3}x_{t-2}y \cdots yx_1x_2 \cdots x_{t-2}yx_{s_1}x_{s_2} \cdots x_{s_j}y.$$

Note that  $x(S)$  contains  $t$  copies of  $y$  and at most  $(t-2)(t-1)/2 + t - 2 = (t+1)(t-2)/2$   $x$ 's. Thus  $|x(S)| \leq (t+1)(t + (t+1)(t-2)/2)$  and  $|x(S)|_0 \leq 2t + (t+1)(t-2)/2$ .

To get the bound  $\text{sc}(L) \geq 2^{t-2}$ , we exhibit  $2^{t-2}$  pairwise distinct word under the Myhill-Nerode equivalence relation. Pick two distinct subsets of  $T$ , say  $R$  and  $S$ . Since  $R \neq S$ , there exists an element in one not contained in the other. Without loss of generality, let  $m \in R$ ,  $m \notin S$ . By the proof of Theorem 8 we have  $x(R)1^{t-m} \in A^*$  but  $x(S)1^{t-m} \notin A^*$ . Since  $L \subseteq A^*$ ,  $x(S)1^{t-m} \notin L$ . It remains to see  $x(R)1^{t-m} \in L$ .

Since  $x(R)1^{t-m} \in A^*$ , there exists a factorization of  $x(R)1^{t-m}$  in terms of elements of  $A$ . However,

$$\begin{aligned} |x(R)1^{t-m}| &\leq |x(R)| + t \\ &\leq (t+1)(t + (t+1)(t-2)/2 + t) \end{aligned}$$

so any factorization of  $x(R)1^{t-m}$  into elements of  $A$  contains at most  $(t+1)(t-2)/2 + 2t$  copies of words other than 0. Similarly

$$\begin{aligned} |x(R)1^{t-m}|_0 &\leq |x(R)| \\ &\leq (t+1)(t-2)/2 + 2t \end{aligned}$$

so any factorization of  $x(R)1^{t-m}$  into elements of  $A$  contains at most  $(t+1)(t-2)/2 + 2t$  copies of the word 0. Thus a factorization of  $x(R)1^{t-m}$  into elements of  $A$  is actually contained in  $L$ .  $\square$

**Corollary 11.** *There exists an infinite family of tuples  $(x_1, x_2, \dots, x_k)$  where  $m$ , the total number of symbols, is  $O(t^4)$ , and  $\text{sc}(x_1^* \cdots x_k^*) = 2^{\Omega(t)}$ .*

We now turn to an upper bound on the state complexity of  $S^*$  in the case where the number of words in  $S$  is not specified, but we do have a bound on the length of the longest word.

**Theorem 12.** Let  $S = \{x_1, x_2, \dots, x_k\}$  be a finite set with  $\max_{1 \leq i \leq k} |x_i| = n$ , that is, the longest word is of length  $n$ . Then  $\text{sc}(S^*) \leq \frac{2}{2^{|\Sigma|}-1}(2^n |\Sigma|^n - 1)$ .

*Proof.* The idea is to create a DFA  $M = (Q, \Sigma, \delta, q_0, F)$  that records the last  $n - 1$  symbols seen, together with the set of the possible positions inside those  $n - 1$  symbols where the factorization of the input into elements of  $S$  could end.

Our set of states  $Q$  is defined by  $\{[w, T] : |w| < n, S \subseteq \{0, 1, \dots, |w|\}\}$ . The intent is that the DFA reaches state  $[x, T]$  on input  $y = y_1 y_2 \dots y_i$  if and only if  $|x| = \max(n - 1, i)$ ,  $x$  is a suffix of  $y$ , and

$$T = \{a : 0 \leq a \leq x \text{ and } y_1 y_2 \dots y_{n-a} \in S^*\}.$$

The initial state is  $[\epsilon, \{0\}]$  and the set of final states is  $\{[x, T] : 0 \in T\}$ .

To maintain the invariant, we define our transition function  $\delta$  as follows:

If  $|x| < n - 1$ , then  $\delta([x, T], a) = [xa, U]$  where

$$U = \begin{cases} (T + 1) \cup \{0\}, & \text{if a suffix of length } i + 1 \text{ of } xa \text{ is in } S \text{ for some } i \in T; \\ (T + 1), & \text{otherwise.} \end{cases}$$

If  $|x| = n - 1$ , then  $\delta([bx, T], a) = [xa, U]$  where

$$U = \begin{cases} ((T + 1) - \{n\}) \cup \{0\}, & \text{if a suffix of length } i + 1 \text{ of } bxa \text{ is in } S \text{ for some } i \in T; \\ (T + 1) - \{n\}, & \text{otherwise.} \end{cases}$$

Verification that the construction works is left to the reader. The number of states is  $\sum_{0 \leq i < n} |\Sigma|^i 2^{i+1} = \frac{2}{2^{|\Sigma|}-1}(2^n |\Sigma|^n - 1)$ .  $\square$

## 5 State complexity for two words

In this section we develop formulas bounding the state complexity of  $\{w, x\}^*$  and  $w^* x^*$ . Here, as usual,  $g(x_1, x_2)$  denotes the Frobenius function introduced in Section 1.

We need the following lemma, which is of independent interest and which generalizes a classical theorem of Fine and Wilf [13].

**Lemma 13.** Let  $w$  and  $x$  be nonempty words. Let  $y \in w\{w, x\}^\omega$  and  $z \in x\{w, x\}^\omega$ . Then the following conditions are equivalent:

- (a)  $y$  and  $z$  agree on a prefix of length  $|w| + |x| - \gcd(|w|, |x|)$ ;
- (b)  $wx = xw$ ;
- (c)  $y = z$ .

Furthermore, the bound in (a) is optimal, in the sense that for all pairs of lengths  $(m, n)$  there exists a pair of words  $(|w|, |x|)$  such that  $w^\omega$  and  $x^\omega$  agree on a prefix of length  $|w| + |x| - \gcd(|w|, |x|) - 1$ .

*Proof.* (a)  $\implies$  (b): We prove the contrapositive. Suppose  $wx \neq xw$ . Without loss of generality, we can assume  $\gcd(|w|, |x|) = 1$ , for if not, we group the symbols of  $w$  and  $x$  into blocks of size  $d = \gcd(|w|, |x|)$ , obtaining new words over a larger alphabet whose lengths are relatively prime.

Then we prove that  $y$  and  $z$  differ at a position  $\leq |w| + |x| - 1$ . The proof is by induction on  $|w| + |x|$ .

The base case is  $|w| + |x| = 2$ . Then  $|w| = |x| = 1$ . Since  $wx \neq xw$ , we must have  $w = a$ ,  $x = b$  with  $a \neq b$ . Then  $y$  and  $z$  differ at the 1'st position.

Now assume true for  $|w| + |x| < k$ . We prove it for  $|w| + |x| = k$ . If  $|w| = |x|$  then  $y$  and  $z$  must disagree at the  $|w|$ 'th position or earlier, for otherwise  $w = x$  and  $wx = xw$ , and  $|w| \leq |w| + |x| - 1$ . So, without loss of generality, assume  $|w| < |x|$ . If  $w$  is not a prefix of  $x$ , then  $y$  and  $z$  disagree on the  $|w|$ 'th position or earlier, and again  $|w| \leq |w| + |x| - 1$ .

So  $w$  is a proper prefix of  $x$ . Write  $x = wt$  for some nonempty word  $t$ . Now  $wt \neq tw$ , for if so, then  $wx = wwt = wtw = xw$ . Then  $y = ww \cdots$  and  $z = wt \cdots$ . By induction (since  $|w| + |t| < k$ )  $w^{-1}y$  and  $w^{-1}z$  disagree at position  $|w| + |t| - 1$  or earlier. Hence  $y$  and  $z$  disagree at position  $2|w| + |t| - 1 = |w| + |x| - 1$  or earlier.

(b)  $\implies$  (c): If  $wx = xw$ , then by the theorem of Lyndon-Schützenberger, both  $w$  and  $x$  are powers of a common word  $u$ . Hence  $y = u^\omega = z$ .

(c)  $\implies$  (a): Trivial.

For the optimality statement, the words constructed in the paper [6] suffice.  $\square$

**Theorem 14.** *Let  $w, x \in \Sigma^+$ . Then*

$$\text{sc}(\{w, x\}^*) = \begin{cases} |w| + |x|, & \text{if } wx \neq xw; \\ d(g(|w|/d, |x|/d) + 1) + 2, & \text{if } wx = xw \text{ and } d = \gcd(|w|, |x|). \end{cases}$$

*Furthermore, this bound is tight.*

*Proof.* If  $wx = xw$ , then by a classical theorem of Lyndon and Schützenberger [20], we know there exists a word  $z$  and integers  $i, j \geq 1$  such that  $w = z^i$ ,  $x = z^j$ . Thus  $\{w, x\}^* = \{z^i, z^j\}^*$ . Let  $e = \gcd(i, j)$ . Then  $L = \{z^i, z^j\}^*$  consists of all words of the form  $z^{ke}$  for  $k > g(i/e, j/e)$ , together with some words of the form  $z^{ke}$  for  $0 \leq k < g(i/e, j/e)$ . Thus, as in the proof of Corollary 4, we can accept  $L$  with a “tail” of  $e|z|g(i/e, j/e) + 1$  states and a “loop” of  $e|z|$  states. Adding an additional state as a “dead state” to absorb unused transitions gives a total of  $(e|z|(g(i/e, j/e) + 1) + 2)$  states. Since  $d = e|z|$ , the bound follows.

Otherwise,  $xw \neq wx$ . Without loss of generality, let us assume that  $|w| \leq |x|$ . Suppose  $w$  is not a prefix of  $x$ . Let  $p$  be the longest common prefix of  $w$  and  $x$ . Then we can write  $w = paw'$  and  $x = pbx'$  for  $a \neq b$ . Then we can accept  $\{w, x\}^*$  with a transition diagram that has one chain of nodes labeled  $p$  leading from  $q_0$  to a state  $q$ , and two additional chains leading from  $q$  back to  $q_0$ , one labeled  $aw'$  and one labeled  $bx'$ . Since  $a \neq b$ , this is a DFA. One additional “dead state” might be required to absorb transitions on letters not mentioned. The total number of states is  $|p| + 1 + |w'| + |x'| + 1 \leq |w| + |x|$ .

Finally, suppose  $|w| \leq |x|$  and  $w$  is a prefix of  $x$ . We claim it suffices to bound the longest common prefix between any word of  $w\{w, x\}^*$  and  $x\{w, x\}^*$ . For if the longest common prefix is of length  $b$ , we can distinguish between them after reading  $b + 1$  symbols. The  $b + 1$ 'th symbol must be one of two possibilities, and we can use back arrows in the transition diagram to the appropriate state. We may need one additional state as a “dead state”, so the total number of states needed is  $b + 2$ . But from Lemma 5, we know  $b \leq |w| + |x| - 2$ .  $\square$

**Theorem 15.** *Let  $w, x \in \Sigma^+$ . Then*

$$\text{sc}(w^*x^*) = \begin{cases} |w| + 2|x|, & \text{if } wx \neq wx; \\ d(g(|w|/d, |x|/d) + 1) + 2, & \text{if } wx = xw \text{ and } d = \gcd(|w|, |x|). \end{cases}$$

*Proof.* Similar to the proof of the previous theorem. Omitted.  $\square$

## 6 Longest word omitted

In this section we assume that  $S = \{x_1, x_2, \dots, x_k\}$  for finite words  $x_1, x_2, \dots, x_k$ , and  $S^*$  is co-finite. We first obtain an upper bound on the length of the longest word not in  $S^*$ .

**Theorem 16.** *Suppose  $|x_i| \leq n$  for all  $i$ . Then if  $S^*$  is co-finite, the length of the longest word not in  $S^*$  is  $< \frac{2}{2^{|\Sigma|}-1}(2^n|\Sigma|^n - 1)$ .*

*Proof.* Given  $S$ , construct the DFA accepting  $S^*$  by the construction of Theorem 12. The resulting DFA has  $q = \frac{2}{2^{|\Sigma|}-1}(2^n|\Sigma|^n - 1)$  states. Now change the “finality” of each state, so a final state becomes non-final and vice versa. This new DFA accepts  $\overline{S^*}$ . Then the longest word accepted is the length of a longest path to a final state, which is at most  $q - 1$ .  $\square$

In the rest of this section we show that the length of the longest word not in  $S^*$  can be exponentially long in  $n$ . We need several preliminary results first.

We say that  $x$  is a *proper prefix* of a word  $y$  if  $y = xz$  for a nonempty word  $z$ . Similarly, we say  $x$  is a *proper suffix* of  $y$  if  $y = zx$  for a nonempty word  $z$ .

**Proposition 17.** *Let  $S$  be a finite set of nonempty words such that  $S^*$  is co-finite, and  $S^* \neq \Sigma^*$ . Then for all  $x \in S$ , there exists  $x' \in S$  such that  $x$  is a proper prefix of  $x'$ , or vice versa. Similarly, for all  $x \in S$ , there exists  $x' \in S$  such that  $x$  is a proper suffix of  $x'$ , or vice versa.*

*Proof.* Let  $x \in S$ . Since  $S^* \neq \Sigma^*$ , there exists  $v \in \overline{S^*}$ . Since  $S^*$  is co-finite,  $S^* \cap x^*v$  is nonempty. Let  $i \geq 0$  be the smallest integer such that  $x^i v \in S^*$ ; then  $i \geq 1$ , for otherwise  $v \in S^*$ . Since  $x^i v \in S^*$ , there exist  $y_1, y_2, \dots, y_j \in S$  such that  $x^i v = y_1 y_2 \dots y_j$ . Now  $y_1 \neq x$ , for otherwise by cancelling an  $x$  from both sides, we would have  $x^{i-1} v \in S^*$ , contradicting the minimality of  $i$ . If  $|x| < |y_1|$ , then  $x$  is a proper prefix of  $y_1$ , while if  $|x| > |y_1|$ , then  $y_1$  is a proper prefix of  $x$ .

A similar argument applies for the result about suffixes.  $\square$

Next, we give two lemmas that characterize those sets  $S$  such that  $S^*$  is co-finite, when  $S$  is a set  $S$  containing words of no more than two distinct lengths.

**Lemma 18.** *Suppose  $S \subseteq \Sigma^m \cup \Sigma^n$ ,  $0 < m < n$ , and  $S^*$  is co-finite. Then  $\Sigma^m \subseteq S$ .*

*Proof.* If  $S^* = \Sigma^*$ , then  $S$  must contain every word  $x$  of length  $m$ , for otherwise  $S^*$  would omit  $x$ . So assume  $S^* \neq \Sigma^*$ .

Let  $x \in \Sigma^m$ . Then  $S^* \cap x\Sigma^*$  is nonempty, since  $S^*$  is co-finite. Choose  $v$  such that  $xv \in S^*$ ; then there is a factorization  $xv = y_1y_2 \cdots y_j$  where each  $y_i \in S$ . If  $y_1 \in \Sigma^m$ , then  $x = y_1$  and so  $x \in S$ . Otherwise  $y_1 \in \Sigma^n$ . By Proposition 17, there exists  $z \in S$  such that  $y_1$  is a proper prefix of  $z$  or vice versa. But since  $S$  contains words of only lengths  $m$  and  $n$ , and  $y_1 \in \Sigma^n$ , we must have  $z \in \Sigma^m$ , and  $z$  is a prefix of  $y_1$ . Then  $x = z$ , and so  $x \in S$ .  $\square$

**Lemma 19.** *Suppose  $S \subseteq \Sigma^m \cup \Sigma^n$ , with  $0 < m < n < 2m$  and  $S^*$  is co-finite. Then  $\Sigma^l \subseteq S^*$ , where  $l = m|\Sigma|^{n-m} + n - m$ .*

*Proof.* Let  $x$  be a word of length  $l$  that is not in  $S^*$ . Then we can write  $x$  uniquely as

$$x = y_0z_0y_1z_1 \cdots y_{|\Sigma|^{n-m}-1}z_{|\Sigma|^{n-m}-1}y_{|\Sigma|^{n-m}}, \quad (2)$$

where  $y_i \in \Sigma^{n-m}$  for  $0 \leq i \leq |\Sigma|^{n-m}$ , and  $z_i \in \Sigma^{2m-n}$  for  $0 \leq i < |\Sigma|^{n-m}$ .

Now suppose that  $y_iz_iy_{i+1} \in S$  for some  $i$  with  $0 \leq i < |\Sigma|^{n-m}$ . Then we can write

$$x = \left( \prod_{0 \leq j < i} y_jz_j \right) y_iz_iy_{i+1} \left( \prod_{i+1 \leq k \leq |\Sigma|^{n-m}} z_ky_k \right).$$

Note that  $|y_jz_j| = |z_ky_k| = m$ . From Lemma 18, each term in this factorization is in  $S$ . Hence  $x \in S^*$ , a contradiction. It follows that

$$y_iz_iy_{i+1} \notin S \text{ for all } i \text{ with } 0 \leq i < |\Sigma|^{n-m}. \quad (3)$$

Now the factorization of  $x$  in Eq. (2) uses  $|\Sigma|^{n-m} + 1$   $y$ 's, and there are only  $|\Sigma|^{n-m}$  distinct words of length  $n - m$ . So, by the pigeonhole principle, we have  $y_p = y_q$  for some  $0 \leq p < q \leq |\Sigma|^{n-m}$ . Now define

$$\begin{aligned} u &= y_0z_0 \cdots y_{p-1}z_{p-1} \\ v &= y_pz_p \cdots y_{q-1}z_{q-1} \\ w &= y_qz_q \cdots y_{|\Sigma|^{n-m}}, \end{aligned}$$

so  $x = uvw$ . Since  $S^*$  is co-finite, there exists a smallest exponent  $k \geq 0$  such that  $uv^kw \in S^*$ .

Now let  $uv^kw = x_1x_2 \cdots x_j$  be a factorization into elements of  $S$ . Then  $x_1$  is a word of length  $m$  or  $n$ . If  $|x_1| = n$ , then comparing lengths gives  $x_1 = y_0z_0y_1$ . But by (3) we know  $y_0z_0y_1 \notin S$ . So  $|x_1| = m$ , and comparing lengths gives  $x_1 = y_0z_0$ . By similar reasoning we see that  $x_2 = y_1z_1$ , and so on. Hence  $x_j = y_{|\Sigma|^{n-m}-1}z_{|\Sigma|^{n-m}-1}y_{|\Sigma|^{n-m}} \in S$ . But this contradicts (3).

Thus, our assumption that  $x \notin S^*$  must be false, and so  $x \in S^*$ . Since  $x$  was arbitrary, this proves the result.  $\square$

Now we can prove an upper bound on the length of omitted words, in the case where  $S$  contains words of at most two distinct lengths.

**Theorem 20.** *Suppose  $S \subseteq \Sigma^m \cup \Sigma^n$ , where  $0 < m < n < 2m$ , and  $S^*$  is co-finite. Then  $S^* \neq \Sigma^*$ , and the length of the longest word not in  $S^*$  is  $\leq g(m, l) = ml - m - l$ , where  $l = m|\Sigma|^{n-m} + n - m$ .*

*Proof.* Any word in  $S^*$  must be a concatenation of words of length  $m$  and  $n$ . If  $\gcd(m, n) = d > 1$ , then  $S^*$  omits all words whose length is not congruent to 0 (mod  $d$ ), so  $S^*$  is not co-finite, contrary to the hypothesis. Thus  $\gcd(m, n) = 1$ . Then  $S^*$  omits all words of length  $g(m, n)$ , so  $S^* \neq \Sigma^*$ .

By Lemmas 18 and 19, we have  $\Sigma^m \cup \Sigma^l \subseteq S^*$ , where  $l = m|\Sigma|^{n-m} + n - m$ . Hence  $S^*$  contains all words of length  $m$  and  $l$ ; since  $\gcd(m, l) = 1$ ,  $S^*$  contains all words of length  $> g(m, l)$ .  $\square$

*Remark.* We can actually improve the result of the previous theorem to arbitrary  $m$  and  $n$ , thus giving an upper bound in the case where  $S$  consists of words of exactly two distinct lengths. Details will appear in a later version of the paper.

**Corollary 21.** *Suppose  $S \subseteq \Sigma^m \cup \Sigma^n$ , where  $0 < m < n < 2m$  and  $\gcd(m, n) = 1$ . Then  $S^*$  is co-finite iff  $\Sigma^m \subseteq S$  and  $\Sigma^l \subseteq S^*$ , where  $l = m|\Sigma|^{n-m} + n - m$ .*

*Proof.* If  $S^*$  is co-finite, then by Lemmas 18 and 19 we get  $\Sigma^m \subseteq S$  and  $\Sigma^l \subseteq S^*$ . On the other hand, if  $\Sigma^m \subseteq S$  and  $\Sigma^l \subseteq S^*$ , then since  $\gcd(m, l) = 1$ , every word of length  $> g(m, l)$  is contained in  $S^*$ , so  $S^*$  is co-finite.  $\square$

We need one more technical lemma.

**Lemma 22.** *Suppose  $S \subseteq \Sigma^m \cup \Sigma^n$ , where  $0 < m < n < 2m$ , and  $S^*$  is co-finite. Let  $\tau$  be a word not in  $S^*$  where  $|\tau| = n + jm$  for some  $j \geq 0$ . Then  $S^* \cap (\tau\Sigma^m)^{i-1}\tau = \emptyset$  for  $1 \leq i < m$ .*

*Proof.* As before, since  $S^*$  is co-finite we must have  $\gcd(m, n) = 1$ . Define  $L_i = (\tau\Sigma^m)^{i-1}\tau$  for  $1 \leq i < m$ . We prove that  $S^* \cap L_i = \emptyset$  by induction on  $i$ .

The base case is  $i = 1$ . Then  $L_i = L_1 = \{\tau\}$ . But  $S^* \cap \{\tau\}$  by the hypothesis that  $\tau \notin S^*$ .

Now suppose we have proved the result for some  $i$ ,  $i \leq m - 2$ , and we want to prove it for  $i + 1$ . First we show that  $S^* \cap \Sigma^{n-m}L_i = \emptyset$ . Assume that  $uw \in S^*$  for some  $u \in \Sigma^{n-m}$  and  $w \in L_i$ . Then there is a factorization

$$uw = y_1y_2 \cdots y_t \tag{4}$$

where  $y_h \in S$  for  $1 \leq h \leq t$ . Now  $|uw| = n - m + (n + jm + m)(i - 1) + n + jm = n(i + 1) + m(ji + i - 2)$ . Since  $0 < i + 1 < m$ ,  $m$  does not divide  $|uw|$ . Thus at least one of

the  $y_h$  is of length  $n$ , for otherwise (4) could not be a factorization of  $uw$  into elements of  $S$ . Let  $r$  be the smallest index such that  $|y_r| = n$ . Then we have

$$uw = \overbrace{y_1 y_2 \cdots y_{r-1}}^{\text{all of length } m} \overbrace{y_r}^{\text{of length } n} y_{r+1} \cdots y_t.$$

Hence  $|y_1 y_2 \cdots y_r| = m(r-1) + n = mr + n - m$ . Since, by Lemma 18 we have  $\Sigma^m \subseteq S$ , we can write  $y_1 \cdots y_r = uz_1 \cdots z_r$ , where  $z_h \in S$  for  $1 \leq h \leq r$ . Thus

$$\begin{aligned} uw &= y_1 \cdots y_{r-1} y_r y_{r+1} \cdots y_t \\ &= uz_1 \cdots z_r y_{r+1} \cdots y_t; \end{aligned}$$

and, cancelling the  $u$  on both sides, we get  $w = z_1 \cdots z_r y_{r+1} \cdots y_t$ . But each term on the right is in  $S$ , so  $w \in S^*$ . But this contradicts our inductive hypothesis that  $S^* \cap L_i = \emptyset$ .

So now we know that

$$S^* \cap \Sigma^{n-m} L_i = \emptyset; \quad (5)$$

we'll use this fact below.

Now assume that  $S^* \cap L_{i+1} \neq \emptyset$ . Since  $L_{i+1} = \tau \Sigma^m L_i$ , there exists  $\alpha \in \Sigma^m$  and  $w \in L_i$  such that  $\tau \alpha w \in S^*$ . Write  $\tau \alpha w = g_1 g_2 \cdots g_p$ , where  $g_h \in S$  for  $1 \leq h \leq p$ . We claim that  $g_h \in \Sigma^m$  for  $1 \leq h \leq j+1$ . For if not, let  $k$  be the smallest index such that  $|g_k| = n$ . Then by comparing lengths, we have

$$\overbrace{g_1 g_2 \cdots g_{k-1}}^{\text{each of length } m} \overbrace{g_k}^{\text{of length } n} \overbrace{g'_1 g'_2 \cdots g'_{j-k+1}}^{\text{each of length } m}$$

for some  $g'_1, g'_2, \dots, g'_{j-k+1} \in \Sigma^m$ . But this shows  $\tau \in S^*$ , a contradiction. We also have  $g_{j+1} \notin \Sigma^n$ , for otherwise  $\tau = g_1 \cdots g_j g_{j+1} \in S^*$ , a contradiction.

Now either  $g_{j+2} \in \Sigma^m$  or  $g_{j+2} \in \Sigma^n$ . In the former case, by comparing lengths, we see that  $g_{j+3} \cdots g_p \in \Sigma^{n-m} L_i$ . But this contradicts (5). In the latter case, by comparing lengths, we see  $g_{j+3} \cdots g_p \in L_i$ , contradicting our inductive hypothesis. Thus our assumption that  $S^* \cap L_{i+1} \neq \emptyset$  was wrong, and the lemma is proved.  $\square$

Now we are ready to give a class of examples achieving the bound in Theorem 20. We define  $r(n, k, l)$  to be the word of length  $l$  representing  $n$  in base  $k$ , possibly with leading zeros. For example,  $r(11, 2, 5) = 01011$ . For integers  $0 < m < n$ , we define

$$T(m, n) = \{r(i, |\Sigma|, n-m) 0^{2m-n} r(i+1, |\Sigma|, n-m) : 0 \leq i \leq |\Sigma|^{n-m} - 2\}.$$

For example, over a binary alphabet we have  $T(3, 5) = \{00001, 01010, 10011\}$ .

**Theorem 23.** *Let  $m, n$  be integers with  $0 < m < n < 2m$  and  $\gcd(m, n) = 1$ , and let  $S = \Sigma^m \cup \Sigma^n - T(m, n)$ . Then  $S^*$  is co-finite and the longest words not in  $S^*$  are of length  $g(m, l)$ , where  $l = m|\Sigma|^{n-m} + n - m$ .*

*Proof.* First, let's prove that  $S^*$  is co-finite. Since  $\Sigma^m \subseteq S$ , by Corollary 21 it suffices to show that  $\Sigma^l \subseteq S^*$ , where  $l = m|\Sigma|^{n-m} + n - m$ .

Let  $x \in \Sigma^l$ , and write

$$x = y_0 z_0 y_1 z_1 \cdots y_{|\Sigma|^{n-m}-1} z_{|\Sigma|^{n-m}-1} y_{|\Sigma|^{n-m}}$$

where  $y_i \in \Sigma^{n-m}$  for  $0 \leq i \leq |\Sigma|^{n-m}$ , and  $z_i \in \Sigma^{2m-n}$  for  $0 \leq i < |\Sigma|^{n-m}$ .

If  $y_i z_i y_{i+1} \in T(m, n)$  for all  $i$ ,  $0 \leq i < |\Sigma|^{n-m}$ , then since the base- $k$  expansions are forced to match up, we have  $y_i = r(i, |\Sigma|, n - m)$  for  $0 \leq i < |\Sigma|^{n-m}$ . But the longest such word is of length  $m|\Sigma|^{n-m} + n - 2m < l$ , a contradiction. Hence  $y_i z_i y_{i+1} \in S$  for some  $i$ . Thus

$$x = \left( \prod_{0 \leq j < i} y_j z_j \right) y_i z_i y_{i+1} \left( \prod_{i+1 \leq k \leq |\Sigma|^{n-m}} z_k y_k \right).$$

Note that  $|y_j z_j| = |z_k y_k| = m$ . Since  $\Sigma^m \subseteq S$ , this gives a factorization of  $x \in S^*$ . Since  $x$  was arbitrary, we have  $\Sigma^l \subseteq S^*$ .

Now we will prove that  $\tau \notin S^*$ , where

$$\tau := r(0, |\Sigma|, n - m) 0^{2m-n} r(1, |\Sigma|, n - m) 0^{2m-n} \cdots r(|\Sigma|^{n-m} - 1, |\Sigma|, n - m).$$

Note that  $|\tau| = |\Sigma|^{n-m}(n - m) + (|\Sigma|^{n-m} - 1)(2m - n) = m|\Sigma|^{n-m} + n - 2m = l - m$ . Suppose there exists a factorization  $\tau = w_1 w_2 \cdots w_t$ , where  $w_i \in S$  for  $1 \leq i \leq t$ . Since  $|\tau|$  is not divisible by  $m$ , at least one of these terms is of length  $n$ . Let  $k$  be the smallest index such that  $w_k \in \Sigma^n$ . then  $\tau = w_1 \cdots w_{k-1} w_k w_{k+1} \cdots w_t$ . By comparing lengths, we get  $w_i = r(i - 1, |\Sigma|, n - m) 0^{2m-n}$  for  $1 \leq i < k$ . Thus  $w_k = r(k - 1, |\Sigma|, n - m) 0^{2m-n} r(k, |\Sigma|, n - m) \in S \cap \Sigma^n$ . But  $r(k - 1, |\Sigma|, n - m) 0^{2m-n} r(k, |\Sigma|, n - m) \in T(m, n)$ , a contradiction. Thus  $\tau \notin S^*$ .

We may now apply Lemma 22 to get that  $S^*$  omits words of the form  $(\tau 0^m)^{m-2} \tau$ ; these words are of length  $(l - m + m)(m - 2) + l - m = lm - l - m = g(m, l)$ . This completes the proof.  $\square$

**Corollary 24.** *For each odd integer  $n \geq 5$ , there exists a set of binary words of length at most  $n$ , such that  $S^*$  is co-finite and the longest word not in  $S^*$  is of length  $\Omega(n^2 2^{n/2})$ .*

*Proof.* Choose  $m = (n + 1)/2$  and apply Theorem 23.  $\square$

**Example 25.** Let  $m = 3$ ,  $n = 5$ ,  $\Sigma = \{0, 1\}$ . Then  $S = \Sigma^3 + \Sigma^5 - \{00001, 01010, 10011\}$ . Then a longest word not in  $S^*$  is  $00001010011 000 00001010011$ , of length 25.

## 7 Number of omitted words

Recall that  $f(x_1, x_2, \dots, x_k)$  is the classical function which, for positive integers  $x_1, \dots, x_k$  with  $\gcd(x_1, \dots, x_k) = 1$ , counts the number of integers not representable as a non-negative integer linear combination of the  $x_i$ . In this section we consider a generalization of this

function to the setting of a free monoid, replacing the integers  $x_i$  with finite words in  $\Sigma^*$ , and replacing the condition  $\gcd(x_1, \dots, x_k) = 1$  with the requirement that  $\{x_1, \dots, x_k\}^*$  be co-finite.

We have already studied this in the case of a unary alphabet in Section 2, so let us assume that  $\Sigma$  has at least two letters.

**Theorem 26.** *Let  $x_1, x_2, \dots, x_k \in \Sigma^*$  be such that  $|x_i| \leq n$  for  $1 \leq i \leq k$ . Let  $S = \{x_1, x_2, \dots, x_k\}$  and suppose  $S^*$  is co-finite. Then*

$$\mathcal{M} = |\Sigma^* - S^*| \leq \frac{|\Sigma|^q - 1}{|\Sigma| - 1},$$

where  $q = \frac{2}{2^{|\Sigma|}-1}(2^n|\Sigma|^n - 1)$ .

*Proof.* From Theorem 16, we know that if  $S^*$  is co-finite, the length of the longest omitted word is  $< q$ , where  $q = \frac{2}{2^{|\Sigma|}-1}(2^n|\Sigma|^n - 1)$ . The total number of words  $< q$  is  $1 + |\Sigma| + \dots + |\Sigma|^{q-1} = \frac{|\Sigma|^q - 1}{|\Sigma| - 1}$ .  $\square$

We now give an example achieving a doubly-exponential lower bound on  $\mathcal{M}$ .

**Theorem 27.** *Let  $m, n$  be integers with  $0 < m < n < 2m$  and  $\gcd(m, n) = 1$ , and let  $S = \Sigma^m \cup \Sigma^n - T(m, n)$ , where  $T$  was introduced in the previous section. Then  $S^*$  is co-finite and  $S^*$  omits at least  $2^{|\Sigma|^{n-m}} - |\Sigma|^{n-m} - 1$  words.*

*Proof.* Similar to that of Theorem 23.  $\square$

## 8 Conclusion

We have generalized the classical Frobenius problem on integers to the noncommutative setting of a free monoid. Many problems remain, including improving the upper and lower bounds presented here, and examining the computational complexity of the associated decision problems. We will examine these problems in a future paper.
